How Are These Vaccines Like Ramen Noodles?

An interview with **Keith Pardee**, Pharmaceutical Scientist
University of Toronto

The big idea in our lab is that we can run gene circuits outside of cells. And we do that by basically making a soup out of bacteria. So there's no cells, it's just all the machinery that makes a cell work, and we use that machinery to run gene circuits in a test tube.

What's the future promise of your research?

For protein-based drugs like vaccines, the challenge often is that you have to keep the vaccine refrigerated from the time it's made, all the way overseas, on a truck all the way to a village where it's going to be used. There's parts of the world where that's just not possible.

With our system, we've freeze-dried the ability to make that vaccine, and you ship it just like you can do with ramen noodles or soup. And you just add water at the end, and you put the DNA that codes for the vaccine protein in and warm it up to your body temperature. And in a few hours you'll have the vaccine.

As the world's population is growing, we have billions of people who need healthcare, but many of them live on under three dollars a day. So what we use this for is to extend the reach of healthcare to populations that don't have access currently.

TODAY'S RESEARCH. TOMORROW'S REALITY.
